

AWS Bedrock AgentCore vs. TrueFoundry

Feature-Level Pricing Overlap Assessment for the Agentic AI Tooling Landscape

High Overlap

Medium Overlap

Low Overlap

Executive Summary

AgentCore and TrueFoundry sit at different layers of the agentic stack and are priced on fundamentally different models. AgentCore is a usage-metered **build/runtime layer** (compute, sandboxes, memory, evaluation) billed per vCPU-second, GB-hour, token, or API call. TrueFoundry is a tiered-SaaS **governance/gateway layer** (routing, observability, access control) billed per seat/quota bucket with overage rates. Real pricing overlap is concentrated in four areas — **Gateway, Security/Policy, Observability, and Tool/MCP Registry management** — where both platforms meter or gate the same control point. Outside those areas, the two platforms are largely complementary rather than competitive.

AgentCore — Pricing Philosophy

Consumption-based, infrastructure-priced. Every feature bills against a raw resource (vCPU-seconds, GB-hours, tokens, API calls, GB ingested). Cost scales linearly with actual agent behavior — good for variable or spiky fleets, harder to forecast without a cost dashboard.

TrueFoundry — Pricing Philosophy

Tiered SaaS, seat/quota-priced. A flat monthly fee buys a usage bucket (requests, MCP servers, users); overage is billed per-unit past the bucket. Good for budget predictability and procurement simplicity, less efficient if usage is uneven across teams.

Feature-by-Feature Overlap

AGENTCORE FEATURE	TRUEFOUNDRY EQUIVALENT	OVERLAP	WHY
Gateway tool invocation, semantic search, target indexing	MCP Gateway register MCP servers, RBAC, virtual MCP servers, tool-call quota	HIGH	Both are literally "a gateway agents call to reach tools." AgentCore charges \$0.005/1K invocations + \$0.025/1K search + \$0.02/100 tools indexed/month. TrueFoundry bundles this into MCP server slots (5/25/50/custom) and a monthly tool-call quota (50K/1M/5M/custom) inside a flat SaaS fee. Different mechanics (metered vs. tiered-quota), same control point — pick one for MCP tool routing, not both.
Identity OAuth/API-key brokering per tool call	Security & Authentication RBAC, SSO, audit logs	MED	AgentCore Identity is narrowly scoped — issuing tokens/API keys per tool call (\$0.01/1K requests, free via Runtime/Gateway). TrueFoundry's RBAC/SSO is broader org-level access control, not per-call token brokering. Conceptually related (both answer "who can call what") but at different granularity.
Policy Cedar authorization + guardrails on tool calls	Guardrails partner integrations, custom guardrail hooks	MED-HIGH	Both intercept agent actions before execution. AgentCore Policy is metered per authorization check (\$0.000025/request) plus NL-to-Cedar token costs; TrueFoundry's guardrails are feature-gated by plan tier (custom hooks require Pro Plus+) rather than metered per check. Real overlap on "should this call be allowed," but AgentCore is finer-grained/cheaper at scale; TrueFoundry leans toward content/output safety filtering.
Observability CloudWatch traces/spans/logs, PII masking	Observability logs, traces, custom retention, export to storage, alerts	HIGH	Direct overlap. AgentCore bills raw CloudWatch ingestion (\$0.35/GB spans, \$0.50/GB event logs); TrueFoundry bundles logs/traces into plan tiers with retention/export gated by tier. Running both in parallel on the same agent traffic is redundant spend for the same signal — pick one system of record.
Evaluations built-in/custom evaluators, token-metered	No direct equivalent closest: "Feedback on traces" (Pro+)	LOW	TrueFoundry's pricing page has no automated evaluator/scoring product. "Feedback on traces" is manual human tagging, not LLM-as-judge evaluation. This stays AgentCore's lane.
Optimization Insights / Recommendations / Experiments, A/B testing	No equivalent	LOW	No matching capability anywhere in TrueFoundry's pricing table. AgentCore-only territory.
Memory short-term events, long-term records, retrieval	No equivalent	LOW	TrueFoundry has no persistent agent-memory/state-store product listed. Remains AgentCore's lane for stateful agents.
Runtime serverless agent compute, vCPU/GB-hour	No equivalent "AI Deployment Platform" targets model serving, not agent orchestration compute	LOW	TrueFoundry doesn't run your agent compute. Its deployment platform is a separate product targeting model serving/training, not general agent-runtime hosting. No real overlap for where the agent process itself executes.
Browser / Code Interpreter sandboxed execution environments	No equivalent	LOW	No sandbox, headless-browser, or code-execution tooling anywhere in TrueFoundry's stack.
Web Search on AgentCore \$7 per 1,000 queries	No discrete line item	LOW	No native web-search-as-a-service in TrueFoundry. You'd plug a third-party search tool through their Gateway/MCP layer instead — complementary, not overlapping.
AWS Agent Registry (Preview) catalog of MCP servers, agents, skills	Agent Skills Registry named product; pricing not on general pricing page	MED	Strong conceptual overlap — both are a discoverable catalog of agent capabilities — but TrueFoundry's Agent Skills Registry pricing isn't broken out on the general pricing page, so a cost-mechanics comparison is incomplete. Recommend pulling the dedicated registry page before drawing firm conclusions.
Payments (Preview) x402 / stablecoin microtransactions	No equivalent	LOW	No wallet or microtransaction billing layer anywhere in TrueFoundry's offering.
— (no AgentCore equivalent)	AI Gateway universal API, caching, fallbacks, budget/rate limiting, routing	N/A	Flagged for completeness: TrueFoundry's core product is LLM-call routing/caching/cost-control, which sits outside AgentCore's surface entirely. The closer AWS comparison point for this capability is Bedrock itself, not AgentCore.

Reading the overlap column: HIGH = same control point, same billing event, pick one vendor. MED = conceptually related but different granularity or scope — likely complementary with care. LOW = no real competition; one platform simply doesn't offer the capability.

Architectural & Procurement Implications

1. Avoid double governance on Gateway + Observability

The High-overlap zone is where a real "who owns this layer" decision is required. Running both AgentCore Gateway and TrueFoundry MCP Gateway in front of the same tool calls means double metering and double policy enforcement for the same action. The same logic applies to Observability — CloudWatch ingestion charges and TrueFoundry's bundled trace/log retention would both be billing for the same telemetry stream if left unreconciled.

2. Low-overlap zones are complementary, not competitive

Runtime, Memory, Code Interpreter, Browser, Evaluations, Optimization, and Payments are capabilities TrueFoundry's pricing page simply doesn't claim. A likely target architecture runs **AgentCore underneath** for compute, memory, sandboxing, and evaluation, with **TrueFoundry's Gateway/governance layer in front** for unified RBAC, SSO, audit logging, and multi-model routing — particularly relevant for the HIPAA-constrained member/provider-facing application.

3. Pricing-model mismatch affects forecasting, not just feature parity

Because AgentCore meters continuously and TrueFoundry sells fixed buckets with overage, a side-by-side TCO model needs usage projections (sessions/month, tool calls/month, GB telemetry/month) translated into *both* pricing languages before a fair comparison is possible. A flat feature checklist alone will understate AgentCore's cost sensitivity to traffic spikes and overstate TrueFoundry's cost sensitivity to feature depth.

4. Open item before finalizing for ARB

TrueFoundry's **Agent Skills Registry** and **AI Deployment Platform** have dedicated product pages with pricing details not captured on the general /pricing page used for this analysis. If the Registry-vs-AWS-Agent-Registry comparison materially affects the governance framework decision, pull truefoundry.com/agent-skills-registry directly before presenting this table to leadership.
